Abstract

Space-bounded one-way cellular language acceptors (OCA) are investigated. The only inclusion known to be strict in their time hierarchy from real-time to exponential-time is between real-time and linear-time! We show the surprising result that there exists an infinite hierarchy of properly included OCA-language families in that range. A generalization of a method in [9] is shown which provides a tool for proving that languages are not acceptable by OCAs with small time bounds. The hierarchies are established by such a language and a translation result. In addition, a notion of constructibility for CAs is introduced, along with some of its properties. We prove several closure properties of the families in the hierarchy.

Key words: Models of computation, computational complexity, cellular automata, time hierarchies, closure properties.

1 Introduction

Linear arrays of interacting finite automata are models for massively parallel language acceptors. Their advantages are simplicity and uniformity. It has turned out that a large array of not very powerful processing elements operating in parallel can be programmed to be very powerful.
One type of system is of particular interest: the cellular automata whose homogeneously interconnected deterministic finite automata (the cells) work synchronously at discrete time steps obeying one common transition function. Here we are interested in a very simple type of cellular automata. The arrays are real-space bounded, i.e., the number of cells is bounded by the number of input symbols, and each cell is connected to its immediate neighbor to the right only. Due to the resulting information flow from right to left such devices are called one-way cellular automata (OCA). If the cells are connected to their both immediate neighbors the information flow becomes two-way and the device is a (two-way) cellular automaton (CA).

Although parallel language recognition by (O)CAs has been studied for more than a quarter of a century some important questions are still open. In particular, only little is known about proper inclusions in the time hierarchy. Most of the early languages known not to be real-time but linear-time OCA-languages are due to the fact that every unary real-time OCA-language is regular [3]. In [10] and [9] a method has been shown that allows proofs of non-acceptance for non-unary languages in real-time OCAs. Utilizing these ideas the non-closure of real-time OCA-languages under concatenation could be shown.

Since for separating the complexity classes in question there are no other general algebraic methods available, specific languages as potential candidates are of particular interest. In [4] several positive results have been presented. Surprisingly, so far there was only one inclusion in the time hierarchy from real-time to exponential-time known to be strict. It is the inclusion between real-time and linear-time languages. In [1] the existence of a non-real-time OCA-language which is acceptable in \((n + \log(n))\)-time has been proved yielding a lower upper bound for the strict inclusion. Another valuable tool for exploring the OCA time hierarchy is the possible linear speed-up [6] from \(n + r(n)\) to \(n + \epsilon \cdot r(n)\) for \(\epsilon > 0\).

One contribution of the present paper is to show that there exists an infinite time hierarchy of properly included language families. These families are located in the range between real-time and linear-time. The surprising result covers the lower part of the time hierarchy in detail. Another contribution is the investigation of several closure properties of the language families in the hierarchy.

The paper is organized as follows: In Section 2 we define the basic notions and the model in question. Since for almost all infinite hierarchies in complexity theory the constructibility of the bounding functions is indispensable, in Section 3 we present a new notion of constructibility in OCAs and prove that it covers a wider range of functions than the usual approach. Section 4 is devoted to a generalization of the method in [9] to time complexities beyond
real-time. This key tool is utilized to obtain a certain language not acceptable with a given time bound. In Section 5 the corresponding proper inclusion is extended to an infinite time hierarchy by translation arguments. Finally, in Section 6 some closure properties are investigated.

2 Basic notions

We denote the positive integers \( \{1, 2, \ldots\} \) by \( \mathbb{N} \) and the set \( \mathbb{N} \cup \{0\} \) by \( \mathbb{N}_0 \). The empty word is denoted by \( \lambda \) and the reversal of a word \( w \) by \( w^R \). For the length of \( w \) we write \( |w| \). We use \( \subseteq \) for inclusions and \( \subset \) if the inclusion is strict. For a function \( f : \mathbb{N}_0 \to \mathbb{N} \) we denote its \( i \)-fold composition by \( f[i] \), \( i \in \mathbb{N} \). If \( f \) is increasing then its inverse is defined according to \( f^{-1}(n) = \min\{m \in \mathbb{N} \mid f(m) \geq n\} \). As usual, we define the set of functions that grow strictly less than \( f \) by \( o(f) = \{g : \mathbb{N}_0 \to \mathbb{N} \mid \lim_{n \to \infty} \frac{g(n)}{f(n)} = 0\} \). In terms of orders of magnitude \( f \) is an upper bound of the set \( O(f) = \{g : \mathbb{N}_0 \to \mathbb{N} \mid \exists n_0, c \in \mathbb{N} : \forall n \geq n_0 : g(n) \leq c \cdot f(n)\} \). Conversely, \( f \) is a lower bound of the set \( \Omega(f) = \{g : \mathbb{N}_0 \to \mathbb{N} \mid f \in O(g)\} \).

A one-way resp. two-way cellular automaton is a linear array of identical deterministic finite state machines, sometimes called cells, which are connected to their nearest neighbor to the right resp. to their both nearest neighbors. The array is bounded by cells in a distinguished so-called boundary state. For convenience we identify the cells by positive integers. The state transition depends on the current state of each cell and the current state(s) of its neighbor(s). The transition function is applied to all cells synchronously at discrete time steps. Formally:

**Definition 1** A one-way cellular automaton (OCA) is a system \( \langle S, \delta, \#, A, F \rangle \) where

1. \( S \) is the finite, nonempty set of cell states,
2. \( \# \notin S \) is the boundary state,
3. \( A \subseteq S \) is the nonempty set of input symbols,
4. \( F \subseteq S \) is the set of accepting (or final) states, and
5. \( \delta : (S \cup \{\#\})^2 \to S \) is the local transition function.

![Fig. 1. A one-way cellular automaton.](image)

If the flow of information is extended to two-way the resulting device is a (two-way) cellular automaton (CA) and the local transition function maps from \( (S \cup \{\#\})^3 \) to \( S \).
A configuration of a cellular automaton at some time $t \geq 0$ is a description of its global state, which is actually a mapping $c_t : \{1, \ldots, n\} \to S$ for $n \in \mathbb{N}$.

The configuration at time 0 is defined by the initial sequence of states. For a given input $w = a_1 \cdots a_n \in A^+$ we set $c_{0,w}(i) = a_i$ for $1 \leq i \leq n$. During a computation the (O)CA steps through a sequence of configurations whereby successor configurations are computed according to the global transition function $\Delta$:

Let $c_t$ for $t \geq 0$ be a configuration, then its successor configuration is as follows:

$$
c_{t+1} = \Delta(c_t) \iff$$

$$c_{t+1}(1) = \delta(\#, c_t(1), c_t(2))$$

$$c_{t+1}(i) = \delta(c_t(i-1), c_t(i), c_t(i+1)), i \in \{2, \ldots, n-1\}$$

$$c_{t+1}(n) = \delta(c_t(n-1), c_t(n), \#)$$

for CAs and correspondingly for OCAs. Thus, $\Delta$ is induced by $\delta$.

If the state set is a Cartesian product of some smaller sets $S = S_0 \times S_1 \times \cdots \times S_r$, we will use the notion register for the single parts of a state.

An input $w$ is accepted by an (O)CA if at some time $i$ during its course of computation the leftmost cell enters an accepting state.

**Definition 2** Let $M = \langle S, \delta, \#, A, F \rangle$ be an (O)CA.

1. An input $w \in A^+$ is accepted by $M$ iff there exists a time step $i \in \mathbb{N}$ such that $c_i(1) \in F$ holds for the configuration $c_t = \Delta^i(c_{0,w})$.
2. $L(M) = \{w \in A^+ \mid w \text{ is accepted by } M\}$ is the language accepted by $M$.
3. Let $t : \mathbb{N} \to \mathbb{N}$, $t(n) \geq n$, be a mapping. If all $w \in L(M)$ can be accepted with at most $t(|w|)$ time steps, then $L$ is said to be of time complexity $t$.

The family of all languages that are acceptable by some OCA (CA) with time complexity $t$ is denoted by $\mathcal{L}_t(OCA)$ ($\mathcal{L}_t(CA)$). If $t$ equals the identity function $id(n) = n$, acceptance is said to be in real-time, and if $t$ is equal to $k \cdot id$ for an arbitrary rational number $k \geq 1$, then acceptance is carried out in linear-time. Correspondingly, we write $\mathcal{L}_{rt}((O)CA)$ and $\mathcal{L}_{lt}((O)CA)$.

In the following we are going to prove our main result:
Theorem 3 Let $r_1, r_2 : \mathbb{N} \rightarrow \mathbb{N}$ be two increasing functions. If $r_2 \log(r_2) \in o(r_1)$ and $r_1^{-1}$ is constructible, then

$$L_{n+r_2(n)}(OCA) \subset L_{n+r_1(n)}(OCA)$$

Example 4 Let $0 \leq p < q \leq 1$ be two rational numbers. Clearly, $n^p \cdot \log(n^p)$ is of order $o(n^q)$. In the next section the constructibility of the inverse of $n^q$ will be established. Thus, an application of Theorem 3 yields the strict inclusion

$$L_{n+n^p}(OCA) \subset L_{n+n^q}(OCA)$$

Example 5 Let $i < j$ be two positive integers, then $\log^j \cdot \log^{j+1}$ is of order $o(\log^i)$. Again, in the next section the constructibility of the inverse of $\log^i$ will be established. Thus, an application of Theorem 3 yields the strict inclusion

$$L_{n+\log^i}(OCA) \subset L_{n+\log^j}(OCA)$$

3 Constructible Functions

For the proof of Theorem 3 it will be necessary to control the lengths of words with respect to some internal substructures. The following notion of constructibility expresses the idea that the length of a word relative to the length of a subword should be computable.

Definition 6 A function $f : \mathbb{N} \rightarrow \mathbb{N}$ is constructible if there exists an $\lambda$-free homomorphism $h$ and a language $L \in \mathcal{L}_{rt}(OCA)$ such that

$$h(L) = \{a^{f(n) - n}b^n \mid n \in \mathbb{N}\}$$

Since constructible functions describe the length of the whole word dependent on the length of a subword it is obvious that each constructible function must be greater than or equal to the identity. At a first glance this notion of constructibility might look somehow unusual or restrictive. But $\lambda$-free homomorphisms are very powerful such that the family of (in this sense) constructible functions is very rich, and is, in fact, a generalization of the usual notion. The remainder of this section is devoted to clarify the presented notion and its power.

The next lemma states that we can restrict our considerations to length preserving homomorphisms. The advantage is that for length preserving homomorphisms each word in $L$ is known to be of length $f(m)$ for some $m \in \mathbb{N}$.

Lemma 7 Let $f : \mathbb{N} \rightarrow \mathbb{N}$ be a constructible function. Then there exists a length preserving $\lambda$-free homomorphism $h$ and a language $L \in \mathcal{L}_{rt}(OCA)$ such
that
\[ h(L) = \{a^{f(n)-n}b^n \mid n \in \mathbb{N} \} \]

**PROOF.** Since \( f \) is constructible there exists a \( \lambda \)-free homomorphism \( h' \) and a language \( L' \in \mathcal{L}_{rt}(OCA) \) such that \( h'(L') = \{a^{f(n)-n}b^n \mid n \in \mathbb{N} \} \). In order to prove the assertion it suffices to construct a language \( L \in \mathcal{L}_{rt}(OCA) \) and a length-preserving \( \lambda \)-free homomorphism \( h \) with \( h(L) = h'(L') \). Let \( L' \) be defined over an alphabet \( A = \{a_1, \ldots, a_m\} \) and \( h' \) according to
\[
h'(a_1) = b_{1,1} \cdots b_{1,n_1}, \quad h'(a_2) = b_{2,1} \cdots b_{2,n_2}, \quad \ldots, \quad h'(a_m) = b_{m,1} \cdots b_{m,n_m}
\]
where the symbols \( b_{i,j} \) are not necessarily different. We introduce an alphabet \( B = \{\bar{b}_{1,1}, \ldots, \bar{b}_{1,n_1}, \ldots, \bar{b}_{m,n_m}\} \) of different symbols and define the length-preserving \( \lambda \)-free homomorphism \( h \) by
\[
h(\bar{b}_{i,j}) = b_{i,j}
\]
for \( 1 \leq i \leq m \) and \( 1 \leq j \leq n_i \).

In order to construct \( L \) we define a homomorphism \( \hat{h} \) by
\[
\hat{h}(\bar{b}_{i,1}) = a_i \quad \text{and} \quad \hat{h}(\bar{b}_{i,j}) = \lambda
\]
for \( 1 \leq i \leq m \) and \( 2 \leq j \leq n_i \), and set
\[
L = \hat{h}^{-1}(L') \cap \{\bar{b}_{i,1} \cdots \bar{b}_{i,n_i} \mid 1 \leq i \leq m\}^*
\]
By construction \( h'(L') = h(L) \) follows. Since \( \mathcal{L}_{rt}(OCA) \) is closed under inverse homomorphisms and intersection with regular sets \( L \) belongs to \( \mathcal{L}_{rt}(OCA) \).
\( \square \)

Given an increasing constructible function \( f : \mathbb{N} \to \mathbb{N} \) and a language \( L_a \subseteq A^+ \) acceptable by some OCA with time complexity \( n + r(n) \), where \( r : \mathbb{N} \to \mathbb{N} \), we now define a language that plays an important role in the sequel. Let the language \( L_f \subseteq B^+ \) be a witness for the constructibility of \( f \), i.e., \( L_f \in \mathcal{L}_{rt}(OCA) \) and \( h(L_f) = \{a^{f(n)-n}b^n \mid n \in \mathbb{N} \} \) for a length preserving \( \lambda \)-free homomorphism \( h \). The language
\[
L_1(L_a, L_f) \subseteq (A \cup \{\underline{w}\}) \times B^+
\]
is constructed as follows:

1. The second component of each word \( w \) in \( L_1(L_a, L_f) \) is a word of \( L_f \) that implies that \( w \) is of length \( f(m) \) for some \( m \in \mathbb{N} \).
2. The first component of \( w \) contains exactly \( f(m) - m \) blank symbols and \( m \) non-blank symbols.
The non-blank symbols in the first component of \( w \) form a word in \( L_a \).

The following proposition is used in later sections. Besides, it is an example that demonstrates how to use constructible functions. In Lemma 16 we will prove that the shown bound for the time complexity of \( L_1 \) is minimal.

**Proposition 8** The language \( L_1(L_a, L_f) \) is acceptable by some OCA with time complexity \( n + r(f^{-1}(n)) \).

**PROOF.** We construct an OCA \( \mathcal{A} \) with three registers that accepts \( L_1 \) obeying the time complexity \( n + r(f^{-1}(n)) \).

In its first register \( \mathcal{A} \) verifies that the second component of each word in \( L_1 \) is a word of \( L_f \). By definition of \( L_f \) this can be done in real-time.

In its second register \( \mathcal{A} \) checks that the first component of \( L_1 \) contains exactly \( f(m) - m \) blank symbols. Because it can be verified that the second component of \( L_1 \) belongs to \( L_f \), we know that the first \( f(m) - m \) symbols of the second component are mapped to a’s and the last \( m \) symbols of the second component are mapped to b’s. The task is to check that the number of a’s in the second component is equal to the number of blank symbols in the first component. Therefore, \( \mathcal{A} \) shifts the blank symbols from right to left. Each symbol a in the second component consumes one blank symbol. A signal that goes from the right to the left with full speed can check that no blank symbol has reached the leftmost cell and that each letter a has consumed one blank symbol, i.e., that the number of a’s is equal to the number of blank symbols. The test can be done in real-time.

In order to verify that the non-blank symbols in the first component form a word of \( L_a \) the automaton \( \mathcal{A} \) simulates the OCA that accepts \( L_a \). But for every blank symbol \( \mathcal{A} \) needs one time step in addition as illustrated below. Therefore, \( \mathcal{A} \) needs \( m + r(m) + (f(m) - m) \) steps for the simulation \( (m + r(m) \) time steps for the simulation itself and \( f(m) - m \) time steps delaying time). Substituting \( m = f^{-1}(n) \) completes the proof. \( \square \)

The basic idea for accepting words with OCAs that have blank cells is as follows (cf. Figure 3). Initially, the blank cells are marked as transportation cells. At every time step they simply store the state of their right neighbors in some register. All non-blank cells can be blocked or not. A cell gets blocked if its neighbor is blocked or if its neighbor transports a blocked or blank symbol. A blocked cell gets released if its neighbor is released or transports a released symbol. Blocked cells keep their states and released cells work as usual.
It is easily seen that the total delay of a computation equals the number of blank cells.

![Diagram]

Fig. 3. Transportation cells are marked by $\leftarrow$. The bullet indicates a blocked cell.

Now we prove that the family of constructible functions is very rich. In particular, all Fischer-constructible functions are constructible in the sense of Definition 6. A function $f$ is said to be Fischer-constructible if there exists an unbounded two-way CA such that the initially leftmost cell enters a final state at time $i \in \mathbb{C}_6$ if and only if $i = f(m)$ for some $m \in \mathbb{N}$. Moreover, the CA starts with a configuration in which all cells except the leftmost one are quiescent. Thus, the Fischer-constructibility is an important notion that meets the intuition of constructible functions. For a detailed study of these functions see [7] where also the name has been introduced according to the author of [5].

For example, $n^k$ for $k \in \mathbb{N}$, $2^n$, $n!$, and $p_n$, where $p_n$ is the $n$th prime number, are Fischer-constructible. Moreover, the class is closed under several operations.

**Lemma 9** If a function $f : \mathbb{N} \to \mathbb{N}$ is Fischer-constructible, then it is constructible in the sense of Definition 6.
PROOF. Let $f$ be a Fischer-constructible function. In a first step we prove that \( \{ b^n a^{f(n) - n} \mid n \in \mathbb{N} \} \) is a real-time CA-language.

The leftmost cell of the CA starts the construction of $f$, i.e., it distinguishes the time steps $f(1), f(2), \ldots$ The rightmost cell send a signal to the left. The CA accepts a word of the form $b^* a^*$ if and only if this signal reaches the leftmost cell at time step $f(n)$ for some $n \in \mathbb{N}$ and the number of $b$’s is equal to $n$.

Now a language $L \subseteq (\{a, b\} \times \{a, b, \_\})^*$ is constructed as follows:

1. The first component of each word $w \in L$ belongs to $\{ a^{f(n) - n} b^n \mid n \in \mathbb{N} \}$.
2. The second component is the first component compressed by a factor 2 followed by (pairs of) blank symbols.

$L$ is a real-time OCA-language. A corresponding OCA can easily verify that the first component is of the form $a^* b^*$ and that the second component contains the compressed first component. In addition, it simulates the real-time CA for $\{ b^n a^{f(n) - n} \mid n \in \mathbb{N} \}$ on the left part of its second track. This is possible since $L_{\text{rt}}(\text{CA}) = \mathcal{L}_2 \cdot \mathcal{L}_O(\text{OCA})$. Due to the compression the OCA works in real-time.

Together with the $\lambda$-free homomorphism that maps a word to its first component this proves that $f$ is constructible in the sense of Definition 6. □

**Theorem 10** The class of constructible functions is closed under addition, multiplication and composition.

PROOF. Let $f_1$ and $f_2$ be two constructible functions. Further let $L_1, L_2 \in L_{\text{rt}}(\text{OCA})$ and $h_1, h_2$ be two length preserving homomorphisms with $h_i(L_i) = \{ a^{f_i(n) - n} b^n \mid n \in \mathbb{N} \}$, $1 \leq i \leq 2$. Without loss of generality we assume that $L_1$ and $L_2$ are defined over disjoint alphabets.

In order to prove that $f_1(n) + f_2(n)$ is constructible a real-time OCA-language is constructed by the following description of an acceptor. It performs the following tasks in parallel:

1. It checks that the input is of the form $w_1 w_2$ with $w_i \in L_i$, $1 \leq i \leq 2$. This is possible because $L_1$ and $L_2$ are defined over disjoint alphabets.
2. It computes $h_1(w_1) = a^{f_1(n) - n} b^n$ and $h_2(w_2) = a^{f_2(m) - m} b^m$ and verifies $n = m$. A OCA can compare two numbers because $\{ a^n b^n \mid n \in \mathbb{N} \} \in L_{\text{rt}}(\text{OCA})$.

Together with the homomorphism that maps $w_1$ to $a^{f_1(n)}$ and $w_2$ to $a^{f_2(n) - n} b^n$ this proves that $f_1(n) + f_2(n)$ is constructible. (The homomorphism utilizes the fact that $L_1$ and $L_2$ are defined over disjoint alphabets.)
In order to prove that \( f_1(n)f_2(n) \) is constructible, again, a real-time OCA-language is described by an accepting OCA. It works on an input tape with two registers and verifies that:

1. The first track has the form \( a_1\bot^na_2\bot^na_m\bot^n \), where \( \bot \) is a special symbol not belonging to the alphabets of \( L_1 \) and \( L_2 \). (Once again the OCA has to compare numbers.)
2. \( a_1a_2\cdots a_m \) is a word in \( L_1 \). (The OCA can ignore the blank characters.)
3. The second track has the form \( \bot\cdots\bot w_2 \) with \( w_2 \in L_2 \).
4. The non-blank part of the second track has length \( n + 1 \), i.e., the first component of the non-black part is \( a_m\bot^n \).
5. \( n_1 = n_2 \) after computing \( h_1(a_1a_2\cdots a_m) = a^{f_1(n_1)−n_1}b^{n_1} \) and \( h_2(w_2) = a^{f_2(n_2)−n_2}b^{n_2} \).

Together with the homomorphism that applies \( h_2 \) to the second track and maps all blank symbols on the second track to \( a \) this proves that \( f_1(n)f_2(n) \) is constructible.

In order to prove that \( f_1(f_2(n)) \) is constructible the accepting real-time OCA verifies that:

1. The first component of its input is a word \( w_1 \in L_1 \).
2. The second component has the form \( \bot\cdots\bot w_2 \) with \( w_2 \in L_2 \).
3. \( |w_2| = n \) after computing \( h_1(w_1) = a^{f_1(n)−n}b^n \).

By the same homomorphism as in the previous part we see that \( f_1(f_2(n)) \) is constructible. \( \square \)

### 4 Equivalence Classes

To prove lower bounds for the time complexity we generalize a lemma shown in [9] which gives a necessary condition for a language to be real-time acceptable by a OCA. At first we need the following definition:

**Definition 11** Let \( L \) be a language and \( X \) and \( Y \) be two sets of words. Two words \( w \) and \( w' \) are equivalent with respect to \( L, X \) and \( Y \) (in short \((L, X, Y)\)-equivalent) if and only if

\[
xwy \in L \iff xw'y \in L
\]

for all \( x \in X \) and \( y \in Y \).

Let \( L_d \subset \{0, 1, (,), |\}^+ \) be a language whose words are of the form

\[
x(x_1|y_1)\cdots(x_n|y_n)y
\]
where \( x, x_i, y, y_i \in \{0, 1\}^* \) for \( 1 \leq i \leq n \), and \( (x \mid y) = (x_i \mid y_i) \) for at least one \( i \in \{1, \ldots, n\} \).

The language \( L_d \) can be thought of as a dictionary. The task for the OCA is to check whether the pair \( (x \mid y) \) appears in the dictionary or not.

**Proposition 12** Let \( X = Y = \{0, 1\}^* \). Two words \( w = (x_1 \mid y_1) \cdots (x_n \mid y_n) \) and \( w' = (x'_1 \mid y'_1) \cdots (x'_m \mid y'_m) \) are equivalent with respect to \( L_d \), \( X \) and \( Y \) if and only if \( \{(x_1 \mid y_1), \ldots, (x_n \mid y_n)\} = \{(x'_1 \mid y'_1), \ldots, (x'_m \mid y'_m)\} \).

**PROOF.** First assume that the two sets are equal. Let \( x \in X \) and \( y \in Y \), then \( xwy \in L_d \) implies \( (x \mid y) = (x_i \mid y_i) \) for some \( i \). Since the two sets are equal we have \( (x \mid y) = (x'_j \mid y'_j) \) for some \( j \). Therefore, \( xwy \in L_d \) implies \( xw'y \in L_d \) and vice versa, i.e., \( w \) and \( w' \) are \((L_d, X, Y)\)-equivalent.

Now assume the two sets are not equal. Without loss of generality we can assume that there exist \( x \in X \) and \( y \in Y \) with \( (x \mid y) = (x_i \mid y_i) \) for some \( i \), but \( (x \mid y) \neq (x'_j \mid y'_j) \) for all \( j = 1, \ldots, m \). Then \( xwy \in L_d \) but \( xw'y \notin L_d \) and, thus, \( w \) and \( w' \) are not \((L_d, X, Y)\)-equivalent. \( \square \)

Now we are prepared to formulate the lemma we are going to use in order to prove lower bounds for the time complexities.

**Lemma 13** Let \( r : \mathbb{N} \to \mathbb{N} \) be an increasing function, \( L \in \mathcal{L}_{n+r(n)}(\text{OCA}) \) and \( X = \{a_1, \ldots, a_p\}^{m_1} \) and \( Y = \{b_1, \ldots, b_q\}^{m_2} \) be two sets of words for positive integers \( p, q, m_1 \) and \( m_2 \). There exists an integer \( s \in \mathbb{N} \) such that the number \( N \) of \((L, X, Y)\)-equivalence classes of the words at most of length \( n - m_1 - m_2 \) is bounded by

\[
N \leq s^{\left|X\right|s^{(m_2+r(n))\left|Y\right|}}
\]

**PROOF.** Let \( s \) be the minimal number of states needed by a OCA to accept \( L \) in \( n + r(n) \) time steps. Let \( A \) be such a OCA with state set \( S \).

We consider the computation of \( A \) on the word \( xwy \) for some \( x \in X \) and \( y \in Y \). After \( |w| \) time steps the interesting part of the configuration of \( A \) can be described by \( f_w(x)f'_w(y) \) where (cf. Figure 4)

1. \( f_w(x) \in S^* \) and \( f'_w(y) \in S^* \).
2. \( |f_w(x)| = |x| \) and \( |f'_w(y)| = y + r(n) \). During the remaining \( |xwy| + r(|xwy|) - |w| \leq |x| + |y| + r(n) \) time steps the result of the computation of \( A \) depends only on the states of the \( |x| + |y| + r(n) \) leftmost cells.
3. \( f'_w(y) \) depends only on \( w \) and \( y \) since no information can move from left to right.
(4) \( f_w(x) \) depends only on \( w \) and \( x \) since during \(|w|\) time steps only the leftmost \(|x| + |w|\) cells can influence the states of the leftmost \(|x|\) cells.

\[ 
\begin{array}{c}
  x \\
  w \\
  y \\
  r(xwxy) \\
\end{array} 
\]

Fig. 4. OCA computation in the proof of Lemma 13.

If \( f_w(x) = f_w'(x) \) and \( f_w'(y) = f_w'(y) \) for all \( x \in X \) and \( y \in Y \), then \( w \) and \( w' \) are equivalent with respect to \( L, X \) and \( Y \). Thus, if \( w \) and \( w' \) are not equivalent, then \( f_w \neq f_w' \) or \( f_w' \neq f_w' \).

Now we count the number of functions \( f_w \) and \( f_w' \). Since \( f_w' \) maps \( Y \) into the set \( S^{m_2+r(n)} \) which contains \( \bar{s}^{m_2+r(n)} \) elements, the number of different functions \( f_w' \) is bounded by \( (\bar{s}^{m_2+r(n)})^{|Y|} \).

We can utilize the nature of OCAs to give a more precise upper bound for the number of different functions \( f_w \) that map \( X \) into the set \( S^{m_1} \). If a word \( x = x_{m_1} \cdots x_1 \) is mapped to \( s_{m_1} \cdots s_1 \) then due to the one-way information flow \( s_i \) depends on \( x_i \cdots x_1 \) only. Thus, for \( s_i \) there are at most \( \bar{s}^{p_i} \) different (sub-)functions. It follows that the number of different functions \( f_w \) is bounded by

\[
\prod_{i=1}^{m_1} \bar{s}^{p_i} < \bar{s}^{p_{m_1} + 1}
\]

For \( s = \bar{s}^p \) we obtain \( \bar{s}^{p_{m_1} + 1} = s^{p_{m_1}} = s^{|X|} \).

Since \( s \geq \bar{s} \) and each upper bound on the number of pairs \( (f_w, f_w') \) is also an upper bound on the number of \( (L, X, Y) \)-equivalence classes the lemma follows. \( \square \)

In the previous lemma the sets of words \( X \) and \( Y \) are in some sense complete with respect to the underlying alphabets. In the general case where \( X \) and \( Y \) are arbitrary sets of words we obtain a slightly weaker bound:

**Lemma 14** Let \( r : \mathbb{N} \to \mathbb{N} \) be an increasing function, \( L \in \mathcal{L}_{n+r(n)}(OCA) \) and \( X \) and \( Y \) be two sets of words. Let \( s \) be the minimal number of states needed by an OCA to accept \( L \) in \( n + r(n) \) time steps.
If all words in $X$ are of length $m_1$ and all words in $Y$ are of length $m_2$, then the number $N$ of $(L, X, Y)$-equivalence classes of the words at most of length $n - m_1 - m_2$ is bounded by

$$N \leq s^{m_1 |X|} s^{(m_2 + r(n)) |Y|}$$

For the special case $L \in \mathcal{L}_{rt}(OCA)$ the lemma has been shown in [9].

Now we apply the lemma to the language $L_d$.

**Proposition 15** Let $r : \mathbb{N} \rightarrow \mathbb{N}$ be an increasing function. If $r(n) \log(r(n)) \in o(n)$, then $L_d$ is not acceptable by any OCA with time complexity $n + r(n)$ but $L_d$ belongs to $\mathcal{L}_{lt}(OCA)$.

**Proof.** For fixed $m_1 \in \mathbb{N}$ and $m_2 \in \mathbb{N}$ we investigate all words of the form $(x_1 | y_1) \cdots (x_k | y_k)$ with $x_i \in \{0, 1\}^{m_1}$ and $y_i \in \{0, 1\}^{m_2}$ for all $i \in \{1, \ldots, k\}$ and $(x_i | y_i) \neq (x_j | y_j)$ for $i \neq j$. We call this words of type $(m_1, m_2)$.

Since there are at most $2^{m_1 + m_2}$ different pairs the length of words of type $(m_1, m_2)$ is at most $2^{m_1 + m_2} \cdot (m_1 + m_2 + 3)$.

As it has been shown in Proposition 12 two words are equivalent iff the sets of subwords are equal. Thus, there are $2^{m_1 + m_2}$ words of type $(m_1, m_2)$ which belong to different equivalence classes with respect to $L_d$, $X = \{0, 1\}^{m_1}$ and $Y = \{0, 1\}^{m_2}$. (For each subset of $X \times Y$ there exists one equivalence class.)

Assume $L_d$ belongs to $\mathcal{L}_{n+r(n)}(OCA)$, then an accepting OCA must be able to distinguish all these equivalence classes. By Lemma 13 there must exist a number $s$ such that

$$2^{m_1 + m_2} \leq s^{m_1 s^{(m_2 + r(n))2^{m_2}}}$$

for $n = 2^{m_1 + m_2} \cdot (m_1 + m_2 + 3) + m_1 + m_2$.

In order to obtain a contradiction we proceed as follows:

Approximating the order of $n$ we obtain

$$n \in O(2^{m_1 + m_2} \cdot (m_1 + m_2))$$

Since $r(n) \log(r(n)) \in o(n)$ it holds

$$r(2^{m_1 + m_2}(m_1 + m_2)) \log(r(2^{m_1 + m_2}(m_1 + m_2))) \in o(2^{m_1 + m_2}(m_1 + m_2))$$

Observe, $2^{m_1 + m_2} \log(2^{m_1 + m_2}) = 2^{m_1 + m_2}(m_1 + m_2)$ Therefore, $r(2^{m_1 + m_2}(m_1 + m_2))$ and, hence, $r(n)$ must be of order $o(2^{m_1 + m_2})$. It follows:
∀ \varepsilon' \exists M \forall n > M : r(n) < \varepsilon'2^{m_1+m_2}

In particular

∀ m_2 \forall \varepsilon' \exists M \forall m_1 > M : r(n) < \varepsilon'2^{m_1+m_2}

Choosing \varepsilon' = \frac{\varepsilon}{2^{m_2}} yields

∀ m_2 \forall \varepsilon \exists M \forall m_1 > M : r(n) < \varepsilon2^{m_1}

On the other hand,

∀ m_2 \forall \varepsilon \exists M \forall m_1 > M : m_2 < \varepsilon2^{m_1}

Together we obtain ∀ m_2 \forall \varepsilon \exists M \forall m_1 > M :

\[s^{2m_1}s^{(m_2+r(n))2^{m_2}} < s^{2m_1}s^{(m_2+\varepsilon 2^{m_1})2^{m_2}} < s^{2m_1}s^{2\varepsilon2^{m_1}2^{m_2}}\]

\[= s^{2m_1}s^{2\varepsilon2^{m_1+m_2}} = s^{2m_1+m_2}(2^{-m_2+2\varepsilon}) = 2^{2m_1+m_2}\log(s)(2^{-m_2+2\varepsilon})\]

If we choose \( m_2 \) such that \( 2^{-m_2} < \frac{1}{2\log(s)} \) and \( \varepsilon \) such that \( 2\varepsilon < \frac{1}{2\log(s)} \), then there exists \( M \) such that for all \( m_1 > M \):

\[s^{2m_1}s^{(m_2+r(n))2^{m_2}} < 2^{2m_1+m_2}\log(s)(2^{-m_2+2\varepsilon}) < 2^{2m_1+m_2}\]

This is a contradiction, thus, \( L \) is not acceptable by an OCA in \( (n+r(n))\)-time.

To see that \( L \) is acceptable in linear-time, we construct an appropriate OCA. Starting with an input word of the form \( x(x_1|y_1)\cdots(x_m|y_m)y \) the OCA shifts the subword \( y \) with full speed to the left. During the first \( n \) time steps the OCA marks all pairs \( (x_i|y_i) \) with \( y_i = y \). Each marked pair starts moving to the left with half speed. Each time a pair \( (x_i|y) \) reaches the left hand side the OCA checks whether \( x_i = x \). The pairs of the form \( (x_i|y) \) reach the leftmost cell sequentially because \( y \) moves with full speed but the pairs of form \( (x_i|y) \) with half speed only. This guarantees that the OCA has sufficient time to check whether \( x = x_i \). Figure 5 illustrates the computation. The basic task for the OCA is to check whether \( y = y_i \). This is equivalent to the acceptance of the real-time OCA-language \( \{w\cdot w \mid w \in \{0,1\}^+\} \). \( \square \)
5 Time Hierarchies

The section is devoted to the proof of the result stated in Theorem 3. The next step towards the proof is a translation lemma which allows to extend a single proper inclusion to a time hierarchy.

**Lemma 16** Let \( t_1, t_2 : \mathbb{N} \to \mathbb{N} \) be two functions and \( L_a \) be a \((n + t_1(n))\)-time OCA-language that is not acceptable by any OCA within \( n + o(t_2(n)) \) time since its equivalence classes are not bounded according to Lemma 13. Further let \( f : \mathbb{N} \to \mathbb{N} \) be a constructible function and \( r_1, r_2 : \mathbb{N} \to \mathbb{N} \) be two functions such that \( r_1(f(n)) \in \Omega(t_1(n)) \) and \( r_2(f(n)) \in o(t_2(n)) \). Then

\[
L_{n+r_2(n)}(\text{OCA}) \subset L_{n+r_1(n)}(\text{OCA})
\]

**PROOF.** For \( f(n) \in O(n) \) we have \( r_2(O(n)) \in o(t_2(n)) \) what implies \( r_2(n) \in o(t_2(n)) \) and, thus, \( L_a \notin L_{n+r_2(n)}(\text{OCA}) \). Conversely, \( r_1(O(n)) \in \Omega(t_1(n)) \) and, therefore, \( r_1(n) \in \Omega(t_1(n)) \). It follows \( L_a \in L_{n+r_1(n)}(\text{OCA}) \) and, hence, the assertion.

In order to prove the lemma for \( n \in o(f(n)) \) let \( L_f \) be a language that proves the constructibility of \( f \) in Lemma 7. At first we show that we can always find such an \( L_f \) whose words are of the form \( a^nwb^n \) with \( |w| = f(n) - 2n \).

![Fig. 5. Linear-time acceptance of \( L_d \). The black triangles mark the areas where a check of the form \( y_i = y \) takes place. It is easy to see that the black triangels are disjoint, i.e., the checks can be done one after the other with a finite number of states.](image-url)
By \( w/3 \) we denote the word \( w \) compressed by the factor 3, i.e., one symbol of \( w/3 \) is interpreted as three symbols of \( w \).

Now define \( \bar{L}_f \) such that \( a^{f(n)}n - \frac{1}{3}f(n)(w/3)b^n \in \bar{L}_f \) iff \( w \in L_f \). Clearly, the words of \( \bar{L}_f \) are of the desired form since \( n \in o(f(n)) \). Moreover, there exists a trivial \( \lambda \)-free, length preserving homomorphism that maps \( \bar{L}_f \) to \( \{a^{f(n)}n b^n \mid n \in \mathbb{N}\} \). Also, \( \bar{L}_f \) belongs to \( \mathcal{L}_{r1}(\text{OCA}) \) since an OCA can verify in real-time that an input \( w \)

1. belongs to \( L_f \),
2. the length of the word \( a^{f(n)}n - \frac{1}{3}f(n)(w/3)b^n \in \bar{L}_f \) is equal to the length of \( w \), and
3. that \( n \) is equal to the number of \( b \)’s in \( h(w) \) where \( h \) denotes the homomorphism that maps \( L_f \) to \( \{a^{f(n)}n b^n \mid n \in \mathbb{N}\} \).

Thus, from now on we may assume w.l.o.g. that the words of \( L_f \) are of the form \( a^nwb^n \) with \( |w| = f(n) - 2n \). From Proposition 8 follows that the language \( L_1 = L_1(L_a, L_f) \) belongs to \( \mathcal{L}_{n+t_1(f^{-1}(n))}(\text{OCA}) \). By the assumption on \( r_1(f(n)) \) we obtain \( r_1(n) = r_1(f(f^{-1}(n))) = \Omega(t_1(f^{-1}(n))) \) and, therefore, \( L_1 \in \mathcal{L}_{n+r_1(n)}(\text{OCA}) \).

It remains to show that \( L_1 \notin \mathcal{L}_{n+r_2(n)}(\text{OCA}) \).

Since \( r_2(f(n)) \in o(t_2(n)) \) and \( L_a \) is not acceptable within \( n + o(t_2(n)) \) time by any OCA, the language \( L_a \) is not acceptable within \( n + r_2(f(n)) \) time by any OCA, either. Due to the assumption, by Lemma 13 for every \( s \in \mathbb{N} \) there must exist sets \( X \) and \( Y \) and an \( n \in \mathbb{N} \) such that all words in \( X \) are of length \( m_1 \), all words in \( Y \) are of length \( m_2 \), and the number of \( (L_a, X, Y) \)-equivalence classes of the words at most of length \( n - m_1 - m_2 \) is not bounded by \( s^{X \mid s^{m_2+r_2(f(n)) \mid Y}} \).

Define

\[
X' = \{ (x_1, a) \cdots (x_{m_1}, a) \mid x = x_1 \cdots x_{m_1} \in X \}
\]

and

\[
Y' = \{ (y_1, b) \cdots (y_{m_2}, b) \mid y = y_1 \cdots y_{m_2} \in Y \}
\]

and for every word \( v = v_1 \cdots v_{n-m_1-m_2} \) a word \( v' \) by

\[
v' = (v_1, w_1) \cdots (v_{n-m_1-m_2}, w_{n-m_1-m_2}) (\omega, w_{n-m_1-m_2+1}) \cdots (\omega, w_{f(n)-m_1-m_2})
\]

where \( a^{m_1}w_1 \cdots w_{f(n)-m_1-m_2}b^{m_2} \) is a word of \( L_f \). (Remember that each word in \( L_f \) starts with \( n \) symbols \( a \) and ends with \( n \) symbols \( b \) and \( m_1 + m_2 \leq n \).)

For \( x \in X \) and \( y \in Y \) let \( x' \) and \( y' \) denote the corresponding words in \( X' \) and \( Y' \).
By construction \( xvy \in L_a \) iff \( x'v'y' \in L_1 \). (The word \( x'v'y' \) belongs to \( L_1 \) if the second component of \( x'v'y' \) is a word in \( L_f \), which is always true, and the first component of \( x'v'y' \) is a word in \( L_a \) concatenated with some blank symbols, i.e., \( xvy \in L_a \).) Thus, the \((L_a, X, Y)\)-equivalence classes have corresponding \((L_1, X', Y')\)-equivalence classes and the number of \((L_1, X', Y')\)-equivalence classes under the words whose length is at most \( f(n) - m_1 - m_2 \) is not bounded by \( s|x|_s(m_2+2r(f(n)))/Y| \).

Applying Lemma 13 with \( L_1, X', Y' \) and \( f(n) \) in place of \( L_a, X, Y \) and \( n \) yields that \( L_1 \notin \mathcal{L}_{n+2r(n)}(OCA) \). This completes the proof. □

Finally the main Theorem 3 is just a combination of the preceding lemmas:

**Theorem 3.** Let \( r_1, r_2 : \mathbb{N} \to \mathbb{N} \) be two increasing functions. If \( r_2 \log(r_2) \in o(r_1) \) and \( r_1^{-1} \) is constructible, then

\[
\mathcal{L}_{n+2r(n)}(OCA) \subset \mathcal{L}_{n+r_1(n)}(OCA)
\]

**PROOF.** Proposition 15 shows that the previously defined language \( L_d \) is acceptable in linear-time but is not acceptable in \( n+2(n) \) time if \( r(n) \log(r(n)) \in o(n) \). Now set \( t_1(n) = n \) and \( t_2 \) such that \( t_2(n) \log(t_2(n)) = n \). Inserting yields \( r(n) \log(r(n)) \in o(t_2(n) \log(t_2(n))) \).

We conclude \( r(n) \in o(t_2(n)) \) and, thus, \( L_d \) is not acceptable in \( n + o(t_2(n)) \) time. In order to apply Lemma 16 we consider the constructible function \( f = r_1^{-1} \).

Clearly, \( r_1(f(n)) = n \in \Omega(n) = \Omega(t_1(n)) \).

Since \( r_2(n) \log(r_2(n)) \in o(r_1(n)) \) we have

\[
 r_2(f(n)) \log(r_2(f(n))) \in o(r_1(f(n))) = o(n) = o(t_2(n) \log(t_2(n)))
\]

We conclude \( r_2(f(n)) \in o(t_2(n)) \).

Now all conditions of Lemma 16 are satisfied and an application proves the assertion \( \mathcal{L}_{n+2r(n)}(OCA) \subset \mathcal{L}_{n+r_1(n)}(OCA) \). □

### 6 Closure Properties

In the following we are exploring some of the closure properties of the OCA-language families in the range between real-time and linear-time.
Our first results in this section deal with Boolean operations. Since the OCAs are space-bounded deterministic devices the positive properties are natural.

**Lemma 17** Let \( r : \mathbb{N} \rightarrow \mathbb{N} \) be a function, then \( \mathcal{L}_{n+r(n)}(OCA) \) is closed under union and intersection.

**PROOF.** Using the same two channel technique of [4] and [8] the assertion can easily be seen. Each cell consists of two registers in which acceptors for both languages are simulated in parallel. \( \square \)

The closure under complement is expected for deterministic devices. But here an input is rejected by not entering an accepting state. So in order to accept the complement of a language the OCA has to calculate the latest time step at which the input would have been accepted. With other words, it has to calculate the time step \( n + r(n) \). The corresponding functions are called computable [2].

**Lemma 18** Let \( r : \mathbb{N} \rightarrow \mathbb{N} \) be a computable function, then \( \mathcal{L}_{n+r(n)}(OCA) \) is closed under complement.

**PROOF.** Let \( \mathcal{A} \) be some \( (n + r(n)) \)-time OCA. A OCA \( \mathcal{A}' \) that accepts the complement of \( L(\mathcal{A}) \) works as follows. On its first track it computes the function \( n + r(n) \). On its second track \( \mathcal{A}' \) simulates \( \mathcal{A} \) for at most \( n + r(n) \) time steps. If during the simulation \( \mathcal{A} \) would become accepting, then the leftmost cell of \( \mathcal{A}' \) changes to a distinguished state from which no accepting state is reachable. So \( \mathcal{A}' \) rejects the input. If, on the other hand, \( \mathcal{A} \) would not become accepting until time step \( n + r(n) \), then \( \mathcal{A}' \) simply accepts its input. \( \square \)

Now we turn to more language specific closure properties. The families are closed under marked concatenation but are not closed under concatenation.

**Lemma 19** Let \( r : \mathbb{N} \rightarrow \mathbb{N} \) be an increasing function, then \( \mathcal{L}_{n+r(n)}(OCA) \) is closed under marked concatenation and marked iteration.

**PROOF.** Let \( \mathcal{A} \) and \( \mathcal{A}' \) be two \( (n + r(n)) \)-time OCAs. A OCA \( \mathcal{A}'' \) that accepts the marked concatenation \( L(\mathcal{A})L(\mathcal{A}') \) with time complexity \( n + r(n) \) has two tracks. Initially all inner cells start to simulate \( \mathcal{A} \) and \( \mathcal{A}' \) in parallel. The rightmost non-border cell identifies itself and starts to simulate \( \mathcal{A}' \) only.
This behavior proceeds to the left such that the cells between the right border and the mark are successively identified.

Analogously, the cell whose right neighbor contains the mark can identify itself. It starts to simulate $A$ only and signals this behavior to the left.

Let $n = n_1 + 1 + n_2$ be the length of the input where the first $n_1$ symbols form a word from $L(A)$ and the last $n_2$ symbols form a word from $L(A')$. In between the words there is exactly one marking symbol. Then the simulation of $A$ takes $n_1 + r(n_1)$ time steps and the simulation of $A'$ takes $n_2 + r(n_2)$ time steps. Since the latter result has to move into the leftmost cell the time complexity of $A''$ is

$$\max\{n_1 + r(n_1), n_2 + r(n_2) + n_1\} + 1$$

In both cases $A''$ obeys the time complexity $n + r(n)$.

The generalization to an arbitrary number of concatenated input words and, thus, to marked iteration is straightforward.

**Lemma 20** Let $r : \mathbb{N} \to \mathbb{N}$ be an increasing function. If $r(n) \log(r(n)) \in o(n)$, then $L_{n+r(n)}(OCA)$ is not closed under concatenation.

**Proof.** Let us consider the language $L_l$ whose words are of the form

$$x \left( x_1 \mid y_1 \right) \cdots \left( x_n \mid y_n \right) (x)$$

where $x, x_i, y_i \in \{0, 1\}^*$ for $1 \leq i \leq n$. Since $\{w \bullet w \mid w \in \{0, 1\}^+\}$ is a real-time OCA-language $L_l$ is a real-time OCA-language. The same holds for the language $L_r$ whose words are of the form

$$y \right) \left( x_1 \mid y_1 \right) \cdots \left( x_n \mid y_n \right) y$$

where $y, x_i, y_i \in \{0, 1\}^*$ for $1 \leq i \leq n$.

It follows $L_l$ and $L_r$ are $(n + r(n))$-time OCA-languages. But the concatenation $L_lL_r$ equals the language $L_d$ which has been proven not to belong to $L_{n+r(n)}(OCA)$ in Proposition 15.

**Corollary 21** Let $r : \mathbb{N} \to \mathbb{N}$ be an increasing function. If $r(n) \log(r(n)) \in o(n)$, then $L_{n+r(n)}(OCA)$ is not closed under iteration.

**Proof.** A word of the form

$$x \left( x_1 \mid y_1 \right) \cdots \left( x_n \mid y_n \right) y$$
where \( x, x_i, y, y_i \in \{0, 1\}^+ \) for \( 1 \leq i \leq n \) belongs to \( L_d \) if and only if it belongs to \( (L_l \cup L_r)^* \). Since the structure of the words in \( L_d \) is regular the structure is a real-time OCA-language. Since \( L_{n+r(n)}(OCA) \) is closed under intersection with regular sets and union the closure under iteration would imply \( L_d \in L_{n+r(n)}(OCA) \) what contradicts Proposition 15. □

Now some closure properties concerning homomorphisms are shown.

**Lemma 22** Let \( r : \mathbb{N} \to \mathbb{N} \) be an increasing function. If \( r(O(n)) \subseteq O(r(n)) \), then \( L_{n+r(n)}(OCA) \) is closed under inverse homomorphisms.

**PROOF.** Let \( L \in L_{n+r(n)}(OCA) \) be a language over some alphabet \( A \) and \( h : B^* \to A^* \) be a homomorphism. A \((n + r(n))\)-time OCA \( A \) which accepts the language \( h^{-1}(L) \) works as follows.

Let \( k = \max\{|h(b)| \mid b \in B\} \) be the maximal length of the symbol images of \( h \). Then \( A \) has \( k \) registers.

Basically, each cell of \( A \) maps its input symbol according to \( h \), stores the image into its registers and simulates the acceptor for \( L \).

Let \( n \) be the length of the input \( w \) of \( A \) and \( m \) be the length of \( h(w) \). We are concerned with two cases.

If some input symbol is mapped to \( \lambda \), the resulting empty registers of the corresponding cell cause a delay until the necessary information for the next simulation step is available (cf. proof of Proposition 8). So the total delay is bounded by the number of empty cells.

On the other hand, if some symbol is mapped to more than one symbol, the registers of the corresponding cell and the registers of its left neighbor can simulate more than one transition during one time step.

The leftmost cell of \( A \) has to simulate at least \( m + r(m) \) transitions. Since it may happen that the rightmost non-empty cell contains only one symbol, \( A \) has to simulate this cell for \( r(m) \) time steps, i.e., \( r(m) \) transitions. After time \( r(m) \) the state of this cell will not influence the overall computation result of the simulated acceptor. Since all the cells on the left simulate as many transitions per time step as possible (depending on the number of filled registers and the number of simulated steps of the right neighbor), \( A \) needs another \( n \) time steps to complete the simulation. Altogether the simulation takes \( n + r(m) \) time steps.

If \( m \leq n \) then \( A \) works fine and trivially obeys the time complexity \( n + r(n) \).
In the second case we have $m > n$. Since $m$ is linearly bounded by $n$, i.e., $m \leq k \cdot n$ for the constant $k$, $n+r(k\cdot n)$ is an upper bound of the time complexity. Due to the assumption there exists a constant $k'$ such that $n+r(k\cdot n) \leq n+k' \cdot r(n)$. By the well-known result in [6] the computation can be sped-up linearly from $n+k' \cdot r(n)$ to $n+\varepsilon \cdot r(n)$ for $\varepsilon > 0$. □

**Lemma 23** Let $r : \mathbb{N} \to \mathbb{N}$ be an increasing function. If $r(n) \log(r(n)) \in o(n)$, then $\mathcal{L}_{n+r(n)}(\text{OCA})$ is not closed under $\lambda$-free homomorphisms.

**PROOF.** Construct a language $L \subseteq \{[\cdot] \times \{0,1,(,)|\}\}^*$ as follows:

1. The second component of each word in $L$ is of the form
   $$x(x_1 | y_1) \cdots (x_n | y_n)y$$

2. The first component is such that exactly one pair $(x_i | y_i)$, $1 \leq i \leq n$, is marked by $\bullet$. All the other registers contain $[\cdot]$.

3. The components of the marked pair match $x$ and $y$, respectively. i.e. $x = x_i$ and $y = y_i$.

Clearly, $L$ is a real-time OCA-language. But the image of $L$ under the $\lambda$-free homomorphism $h : \{[\cdot], \bullet\} \times \{0,1,(,)|\}\}^* \to \{0,1,(,)|\}\}^*$, $h(a,b) = b$, that maps a pair to its second component is the language $L_d$ which does not belong to $\mathcal{L}_{n+r(n)}(\text{OCA})$.

Acknowledgements

The authors are grateful to Véronique Terrier whose valuable comments improved the upper bound in Lemma 13 and thus the tightness of the hierarchy.
